Abstract: *In medical image processing related to the brain tumor Magnetic resonance (MR) images plays important role to detect the tumor but specific brain image segmentation is a not easy and it is one of the time taken process. An automatic process needed to detect the tumor in brain. Recently many researchers are working on the brain tumor segmentation methods but still some improvement is needed. In this paper work is improved for the adaptive local fitting method for efficient segmentation of the brain tumor. In Medical image processing one of the parameter which affects the accuracy is inhomogeneity. In proposed work level set method is used for minimizing the energy function. For this weighted sum of the neighboring pixels is considered based on their comparative reputation. To MR images are used to find the brain tumor. Our method is compared with the other previous methods and it is found that our proposed work gives better results. Results are compared based on performance confusion matrix parameters.*

Keywords: **Magnetic resonance (MRI), Brain tumor, segmentation**

1. INTRODUCTION:

In Medical image processing field segmentation of Magnetic resonance (MR) images for brain tumor detection is useful; many researchers are working on this area. Early detection of the tumor is becoming easy and because of that death rate is reducing. In case of automatic medical diagnosis system MRI images provide good results as compare to the computed tomography. Contingent upon their underlying starting point, cerebrum tumors can be considered as either essential brain tumors or metastatic cerebrum tumors. In essential ones, the inception of the cells are cerebrum tissue cells, wherein metastatic cells become carcinogenic at some other piece of the body and spread into the brain. They are sorted as primary or secondary. An essential cerebrum tumor begins in your mind. Numerous essential cerebrum tumors are considered. Secondary brain tumor, otherwise called a metastatic cerebrum tumor, happens when

malignancy cells spread to your mind from another organ, for example, your breast or lung. Detection of early brain tumor is important to in diagnosis and providing proper measures.

In detection of brain tumor MR images are used. Segmentation of the MR images is one of the crucial tasks. In medical image processing relate to the cancer accuracy of the diagnosis is very important. False results of diagnosis may lead the patient in trouble. Segmentation outcomes may vary from person to person who is expert in that domain. A computerized brain tumor discovery framework should take less time and ought to order the brain MR picture as ordinary or tumorous precisely It ought to be steady and ought to give a framework to radiologist which is plain as day and simple to work Figure 1. Shows the general block diagram for various.

2. RELATED WORK

MRI examine is productive method for finding, it comprise attractive field and radio waves. MRI check doesn't utilize any radiation so it is innocuous for human body [1]. Brain tumor is a collection or mass of abnormal cells in a brain. There are different types of brain tumors, some are cancerous and some are

noncancerous [2]. For brain tumor recognition and division various methodologies have been proposed. suchendra et al. proposed progressive self-sorting out , map based multi scale picture division and utilized parallel fuzzy c-means and neuro fuzzy calculation for brain tumor segmentation. [3]. Loads of calculations have been proposed in written works to accomplish the division results precisely. The grouping based techniques are exceptionally proficient, the image is portioned by bunching strategies like k-means and fuzzy C-means.[4].

The computational time required is the major drawback of this algorithm. To detect tumor thresholding, morphological operations, high pass filtering, histogram equalization and segmentation using connected component labeling was carried out. A methodology proposed that integrates Fuzzy C-Means clustering with marker controlled watershed segmentation algorithm separately for medical image segmentation and that integrates K Means clustering with marker controlled watershed segmentation algorithm. This is the two stage process methodology [5].Image segmentation technique based on Hierarchical clustering technologies, k-means and on K- Medoids technologies proposed in some of the studies [6] . color image segmentation using K- medoids clustering is also proposed [7].

A brain tumor segmentation method is validated on two dimensional MRI data have developed [8] and also, detected tumors are represented in 3-Dimensional view. Using fuzzy clustering technique detect tumors from MR images this technique is proposed in [9]. 3D variation segmentation method is designed by [10]. Based on the region, edge detection, threshold level, the image segmentation techniques are classifies as vector quantization and Hierarchical Self Organizing Map [11].

A brain tumor segmentation technique and approved division on two dimensional MRI information proposed and furthermore distinguished tumors are spoken to in 3-Dimensional view [12]. For automated tumor segmentation an artificial intelligence techniques is used [13,14]. The knowledge- based methods [15] deformable templates-based methods [16,17], integrated edge and region detection [18] are proposed for accurate image segmentation .

3. METHODOLOGY

MRI is one of the clinical picture methods; by and large radiologists use this for the interior design of the human body perception. Investigation of mind conduct and examination should be possible depending on the MR pictures. Picture division in MR pictures is done into fluctuated types, for example, dim matter(GM), White matter(WM), and cerebrospinal liquid (CSF) this is viewed as one of the significant errands in MR picture division. In the clinical pictures, the division can be founded on locale development strategies. This includes the utilization of introductory seed point choice from where the region will develop

and locate the proposed area of interest. Active contour is likewise probably the most ideal choice for the division of pictures. They are of different sorts.

3.1 WEIGHTED LEVEL SET EVOLUTION

For clinical picture division applications dependent on active contour executed utilizing variation level set techniques [20], an assortment of picture data, for example, power, edge, or the surface can be utilized to characterize a goal work. Here, we utilize edge data as the principle picture include that drives the advancing form to the ideal limit.

We utilize the accompanying edge marker capacity to procure data about the powers of edges:

$$g = \frac{1}{1+|\nabla G_\sigma * I|}2 \qquad (1)$$

The energy function for level is shown as:

$$\varepsilon(\phi) = R(\phi) + Length(\phi) + Area(\phi) \qquad (2)$$

R(ϕ) is responsible for managing the shape of level set function.

4. RESULTS

Results are performed considering 50 MR images. In brain tumor detection MR images are used. To describe the performance of the proposed work confusion matrix is used here artificial neural network is used for the classification. The confusion matrix will describe the possible outcome in terms of predicted output. The outcome can be True Negative (TN), True Positive (TP), False Negative (FN) and False Positive (FP).

In this system we can consider following factors

TP = correct positive prediction

TN= correct negative prediction

FP= incorrect positive prediction

FN= incorrect negative prediction

TP Rate: It is calculated as the number of correct positive predictions divided by the total number of positives. It is also called as Sensitivity or Recall.

TP Rate = TP / (TP + FN)

FP Rate: False positive rate (FPR) is calculated as the number of incorrect positive predictions divided by the total number of negatives.

FP Rate = FP / TN + FP

P Rate: It is calculated as the number of correct positive predictions divided by the total number of positive predictions. It is also called as Precision.

P Rate = TP = TP + FP

MR Image	TP Rate	FP Rate	P Rate	JCS Rate	DC Rate
	**0.7078**	**0.1463**	**0.8287**	**0.6174**	**0.7635**

Figure 1 Results for the Previous Method of Adaptive local fitting Algorithm[19]

MR Image	TP Rate	FP Rate	P Rate	JCS Rate	DC Rate
	**0.7078**	**0.1463**	**0.8287**	**0.6174**	**0.7635**

Figure 2 Results for the Proposed Method based on weighted level set

5. CONCLUSION

In medical image processing accurate segmentation of masses is one of the important task. In breast cancer. In brain tumor detection MR images are used. In our proposed method brain tumor segmentation is done considering the inhomogeneity parameter. In this weighted level set method is applied. The overall results shows that there needs some improvement in the accurate tumor detection. In our proposed method level set is used to minimize the energy function. While minimizing the energy function weighted sum of the neighboring pixels is taken into consideration. Based on the edge features the comparative prominence contiguous region is considered. Our proposed method is compared with the previous techniques, results shows that proposed work is giving better results in terms of accuracy. Future work will be evaluated considering large database.
